Can A Cancer Drug Reverse Parkinson's Disease And Dementia?

A hybrid drug known as D-3147 is currently being tested for its ability to improve the symptoms of Parkinson's disease and Alzheimer's disease in a small clinical trial. The drug, developed by researchers at the University of Cambridge, is a combination of a potent dopamine receptor agonist and an NMDA receptor antagonist. The combination of these two drugs is designed to help improve motor function and cognition in people with Parkinson's disease and Alzheimer's disease.

The drug is being tested in a phase 2 trial involving 24 patients with Parkinson's disease and 12 patients with Alzheimer's disease. The results of the trial are expected to be released in the coming months.
